# Aligning ontologies

- Ontology alignment or mapping:
  - The process of determining relationships or correspondences between two or more entities in two or more independent ontologies
  - Use ontologies together by defining a set of “links” (mappings or correspondences)
    - Mappings can be of limited types, i.e. only certain logical relations
- Advantages:
  - Benefit from knowledge encoded in the other ontologies models
  - Enable access from different agents/services and across different collections
  - Partial by nature, does not need to cover the entire ontology

*Alignment*

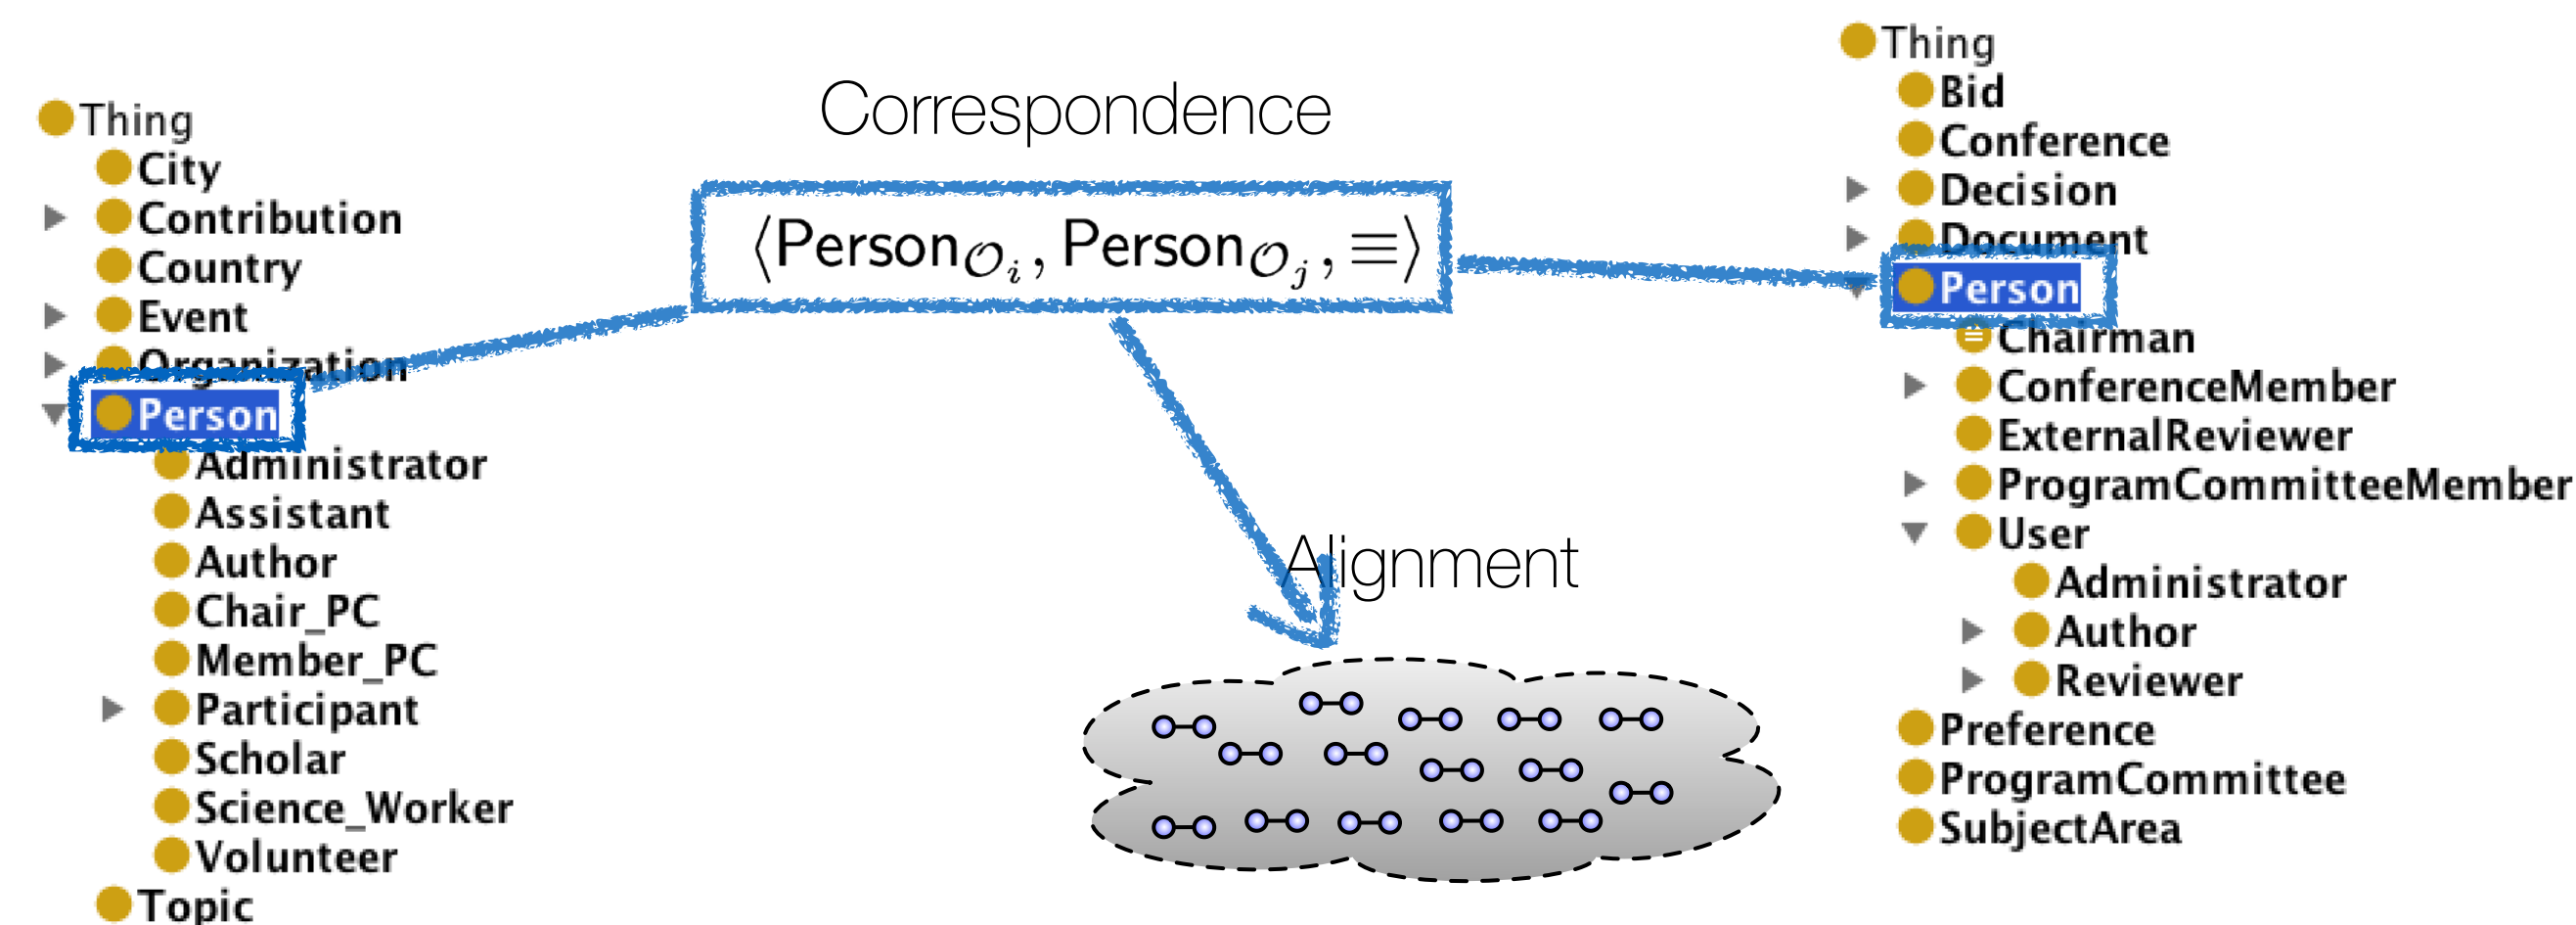

# Ontology alignment: terminology

- Knowledge graph alignment is a type of **ontology alignment** or **ontology matching**.
- To **match** or **align** or **map**: the process that produces an alignment or mapping.
- An **alignment** or **mapping set**: the final output of matching or aligning.
- A **mapping** or **match**: an individual link between related entities (cross reference)

# Atomic ontology alignment

- Given two ontologies  $O$  and  $O'$ , an alignment  $\mathcal{A}$  is the set of correspondences  $c$  between the entities  $e \in O$  and  $e' \in O'$
- A correspondence  $c$  is the tuple  $c = \langle e, e', r, w \rangle$ 
  - $e \in O$  and  $e' \in O'$ , where  $e$  and  $e'$  can be classes, properties, individuals
  - $r = \{=, \sqsubseteq, \perp\}$  and  $w \in [0, \dots, 1]$  is the weight

# Types of correspondence relation between classes/ properties

	OWL	Example
$\equiv$ Equivalence	<code>owl:EquivalentClass</code>	$O:\text{Person} \equiv O':\text{Person}$
$\sqsubseteq$ Subclass	<code>rdfs:subClassOf</code> <code>rdfs:subPropertyOf</code>	$O:\text{Assistant} \sqsubseteq O':\text{User}$
$\perp$ Disjointness	<code>owl:disjointWith</code> , <code>owl:allDisjointClasses</code>	$O:\text{Topic} \perp O':\text{Person}$

# Types of correspondence relation between classes/ properties

	OWL	Example
= Equivalence	<code>owl:sameAs</code>	<code>O:Florence = O':Firenze</code>
≠ Difference	<code>owl:differentFrom</code>	<code>O:John ≠ O':Ringo</code>
∈ Instance	<code>rdf:type</code>	<code>O:Beatles ∈ O':MusicGroup</code>

# Ontology alignment motivation

- An application domain can be modelled with different points of view and purposes
- Ontologies with different naming and modelling conventions exist for the same domain
- Aligning these ontologies will enable interoperability between ontology-based information systems and data migration
- Reusing vocabulary from domain ontologies is a good practice in ontology engineering

## **The Architect**

*When modelling a bridge, important characteristics include:*

*tensile strength  
weight  
load  
etc*

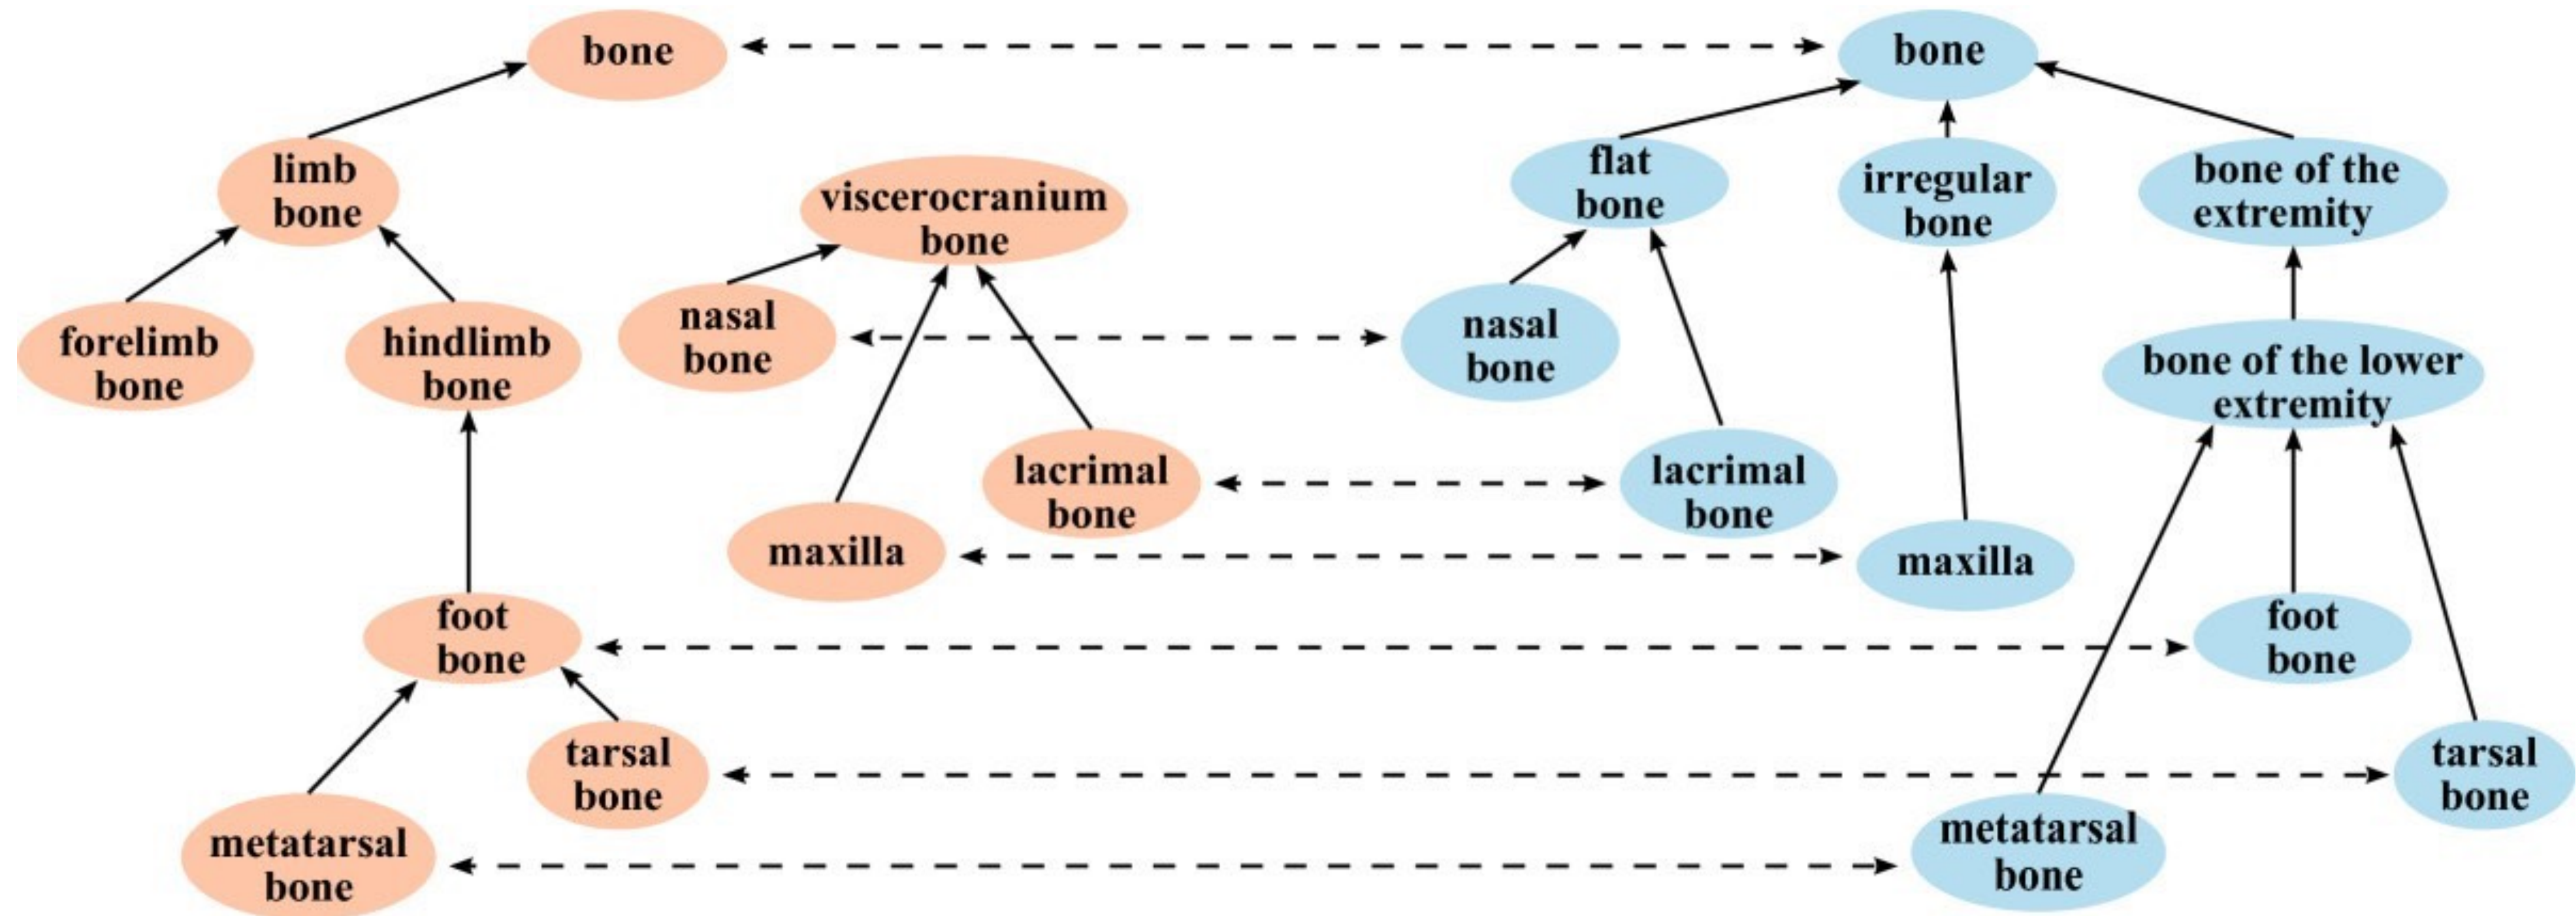

## **The Military**

*When modelling a bridge, important characteristics include:*

*what munitions are required to destroy it!*

# Alignment approaches

- Different alignment approach are available depending on
  - the expressivity of the two ontologies  $O$  and  $O'$
  - The availability of additional inputs to the matching process:
    - Oracles, input alignment and external resources, i.e. Wordnet or BabelNet
  - The entities to match:
    - Only the T-box or schema, i.e. classes and possibly properties
    - Instances
- The majority of current ontology alignment systems align classes, and restrict the relationships to equivalence

# Ontology alignment and the matching process

- Alignments are generated through a *matching process*, a function  $f$ 
  - Input: two ontologies  $O$  and  $O'$ , and an optional input alignment  $A_{input}$ , set of parameters  $par$ , oracles and resources  $res$
  - Output: an alignment  $A'$  between  $O$  and  $O'$ 
    - $A' = f(O, O', A_{input}, par, res)$
    - Set of possible correspondences, with the relationships between entities of  $O$  and  $O'$ 
      - Different multiplicities possible

# Ontologies and Semantic Web

# End Ontology Alignment - Part 2

A word cloud featuring various terms related to the Semantic Web. The most prominent words are 'Semantic Web' in large blue font, 'Systems' in large blue font, and 'Ontology' in large red font. Other visible terms include 'Interoperability' (yellow), 'Services' (purple), 'SPARQL' (purple), 'Interaction' (blue), 'RDF' (purple), 'Knowledge Graph' (green), 'Ontology Alignment' (brown), 'Agents' (green), 'Knowledge' (blue), 'OWL' (purple), 'Linked Open Data' (green), 'Services' (brown), 'Ontology Engineering' (yellow), 'Information' (blue), and 'Semantic Web' (pink). The words are arranged in a dynamic, overlapping manner with various orientations and colors.
