

Proving properties of programs

Using induction to show that a program is correct

What does the following program do?

```
mylist = [1, 2, 6, 3, 5, 6]
```

```
i = 0
```

```
M = mylist[0]
```

```
while i < len(mylist):
```

```
    | M = max(M, mylist[i])
```

```
    | i = i + 1
```

```
print(M)
```

M = 1

i	M	i	M
0	1	5	6
1	2		
2	6		
3	6		
4	6		

Using induction to show that a program is correct

```
mylist = [1, 2, 6, 3, 5, 6]
i = 0
M = mylist[0]
while i < len(mylist):
    M = max(M, mylist[i])
    i = i+1
print(M)
```

Property: After the statement $M = \max(M, \text{mylist}[i])$ gets executed, the value of M is $\max(\text{mylist}[0], \dots, \text{mylist}[i])$.

Proof by induction

Property: After the statement $M = \max(M, \text{mylist}[i])$ gets executed, the value of M is $\max(\text{mylist}[0], \dots, \text{mylist}[i])$.

Base Case: Take $i=0$. Before the statement, $M=\text{mylist}[0]$, so the statement assigns M to be the maximum of $\text{mylist}[0]$ and $\text{mylist}[0]$, which is $\text{mylist}[0]$.

Inductive Step: Assume that the statement is true for $i=m$ for some $m \geq 0$. Now consider $i=m+1$. The statement assigns M to be the maximum of $\text{mylist}[m+1]$ and $\max(\text{mylist}[0], \dots, \text{mylist}[m])$, so after the statement, M is $\max(\text{mylist}[0], \dots, \text{mylist}[m+1])$.

Computing $1 * 2 * \dots * n$

```
def f(n):  
    f = 1  
    for i in range(n):  
        f = f*(i+1)  
    return f
```

1 2 3 ..

$1 \times 2 \times 3 \dots \times n$

```
def g(n):  
    if (n==1):  
        return 1  
    return g(n-1)*n
```

$g(1) \rightarrow 1$

$g(5) \leadsto g(4) \times 5 = 120$

$g(4) \leadsto g(3) \times 4 = 24$

$g(3) \leadsto g(2) \times 3 = 6$

$g(2) \leadsto g(1) \times 2 = 2$

Prove by induction that $g(n) = 1 * 2 * \dots * n$

```
def f(n):  
    if n == 1:  
        return 1  
  
    return g(n-2) * n
```

Prove that $g(n) = n!$

Base case $n=1$

$g(1)$ by lines 2 and 3 is 1

Induction step

Suppose that $g(m) = m!$

Consider $g(m+1)$. The return value
is $g(\underbrace{(m+1)-1}_m) \times (m+1)$

$$\boxed{n = m+1}$$

$$g(m) = 1 \times 2 \times \dots \times m$$

Base case: The initial value
1 in our property

Induction step

Prove That for $\forall m$ if $g(m) = m!$
Then $g(m+1) = (m+1)!$

Strong induction

Strong induction

- Prove that the property holds for the natural number $n = 0$.
- Prove that **if** the property holds for $n = 0, 1, \dots, m$ (and not just for $m!$) **then** it holds for $n = m + 1$.

Can also be used to prove a property for all integers greater than or equal to some particular natural number b

Example: Proof by strong induction

Every natural number $n \geq 2$, is a prime or a product of primes.

Base Case: Take $n = 2$. Then n is a prime number.

Inductive Step: Assume that the property holds for $n = m$ so every number i s.t. $2 \leq i \leq m$ is a prime or a product of primes. Now consider $n = m + 1$.

n	
2	prime
3	prime
4	$2 \cdot 2$
5	prime
6	3×2

$$m+1 = k \cdot l$$

$$\textcircled{k} < \underline{m+1}$$

$$\textcircled{l} < \underline{m+1}$$

$$\left. \begin{array}{l} k > 1 \\ l > 1 \end{array} \right\}$$

$$\left(\begin{array}{l} k \geq 2 \\ l \geq 2 \end{array} \right)$$

k is a prime or a product of primes

l is a prime or a product of primes

$\Rightarrow k \cdot l$ is a product of primes

Example: Number of multiplications

For any integer $n \geq 1$, if x_1, x_2, \dots, x_n are n numbers, then no matter how the parentheses are inserted into their product, the number of multiplications used to compute the product is $n - 1$.

$$\overbrace{\left(\left(\left(x_1 * x_2 \right) * \dots \right) * x_n \right)}$$

$$\underbrace{\left(x_1 * x_2 \dots x_{n/2} \right)}_{\left(n/2 - 1 \right)} * \underbrace{\left(x_{n/2+1} \dots x_n \right)}_{\left(n/2 - 1 \right)} = n - 1$$

Proof continued

$$\begin{array}{c}
 x_1 \dots x_n \\
 \hline
 (x_1 \dots x_l) + (x_{l+1} \dots x_n) \quad l + (n-l) = n \\
 \hline
 \uparrow \quad \quad \quad \uparrow \\
 (l-1) + (n-l-1) + 1 = n-1
 \end{array}$$

Common mistakes

Bad proofs: Arguing from example

An incorrect “proof” of the fact that the sum of any two even integers is even.

This is true because if $m = 14$ and $n = 6$, which are both even, then $m + n = 20$, which is also even.

Bad proofs: Using the same letter to mean two different things

Consider the following “proof” fragment:

Suppose m and n are any odd integers. Then by definition of odd, $m = 2k + 1$ and $n = 2k + 1$ for some integer k .

Bad proofs: Jumping to a conclusion

To jump to a conclusion means to allege the truth of something without giving an adequate reason.

Suppose m and n are any even integers. By definition of even, $m = 2r$ and $n = 2s$ for some integers r and s . Then $m + n = 2r + 2s$. So $m + n$ is even.

Bad proofs: Circular reasoning

To engage in circular reasoning means to assume what is to be proved.

Suppose m and n are any odd integers. When any odd integers are multiplied, their product is odd. Hence mn is odd.

Bad proofs: Confusion between what is known and what is still to be shown

*Suppose m and n are any odd integers. We must show that mn is odd.
This means that there exists an integer s such that*

$$mn = 2s + 1.$$

Also by definition of odd, there exist integers a and b such that

$$m = 2a + 1 \text{ and } n = 2b + 1.$$

Then

$$mn = (2a + 1)(2b + 1) = 2s + 1.$$

So, since s is an integer, mn is odd by definition of odd.

Good practice

State your game plan.

A good proof begins by explaining the general line of reasoning, for example, “We use case analysis” or “We argue by contradiction.”

²*Mathematics for Computer Science* by E. Lehman, F. T. Leighton, and A. R. Meyer.

Keep a linear flow.

Sometimes proofs are written like mathematical mosaics, with juicy titbits of independent reasoning sprinkled throughout. This is not good. The steps of an argument should follow one another in an intelligible order.

A proof is an essay, not a calculation.

Many students initially write proofs the way they compute integrals. The result is a long sequence of expressions without explanation, making it very hard to follow. This is bad. A good proof usually looks like an essay with some equations thrown in. Use complete sentences.

Structure your proof

- **Theorem**—A very important true statement.
- **Proposition**—A less important but still interesting statement.
- **Lemma**—A true statement used to prove other statements.
- **Corollary**—A simple consequence of a theorem or a proposition.

Finish

At some point in a proof, you'll have established all the essential facts you need. Resist the temptation to quit and leave the reader to draw the "obvious" conclusion. Instead, tie everything together yourself and explain why the original claim follows.
