## Flooding/Broadcast

## Broadcast given Spanning Tree

 We start from the case in which a spanning tree of the network is given

- Network G = (V, E)
- $E' \subseteq E$  specifies a spanning tree T = (V, E')
- Root:  $u_0$  (leader)
- Processors know T in a distributed way
- Each  $u_i$  knows:
  - a parent<sub>i</sub>

 $u_8$ 

a set children<sub>i</sub>

## **Broadcast given Spanning Tree**

#### Problem:

- u<sub>0</sub> has some information it wishes to send to all processors
  - e.g., a message (M)
  - additionally all nodes must have terminated in the end

### Solution: Pseudocode

#### Algorithm Spanning tree broadcast

#### State of processor $u_i$ :

- parent<sub>i</sub>: holds a processor index or nil;  $u_i$ 's parent
- $children_i$ : holds a set of processor indices (possibly empty);  $u_i$ 's children
- Boolean  $terminated_i$ : indicates whether  $u_i$  has terminated (1) or not (0)

#### Solution: Pseudocode

Algorithm Spanning tree broadcast Initially  $u_0$  knows  $\langle M \rangle$ 

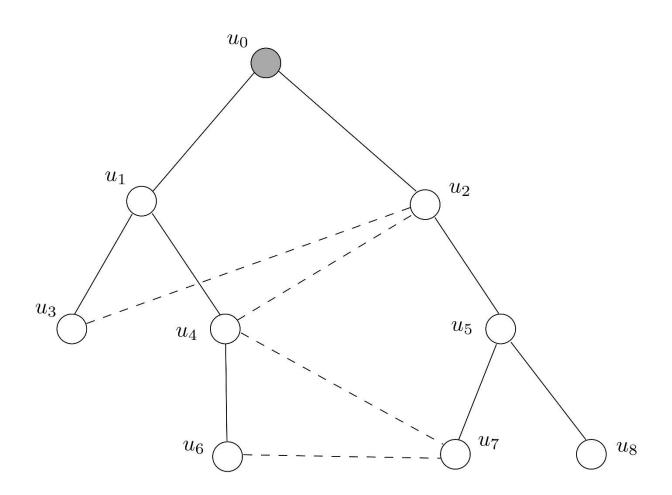

Code for leader  $(u_0)$ : send  $\langle M \rangle$  to all children terminate

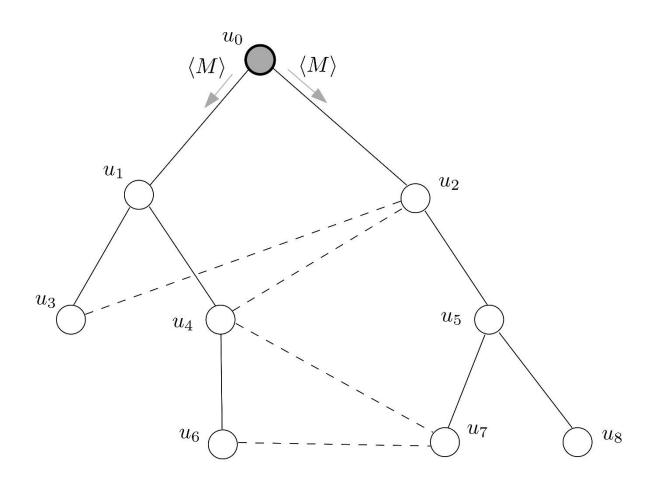

Code for non-leader:

upon receiving (M) from parent:

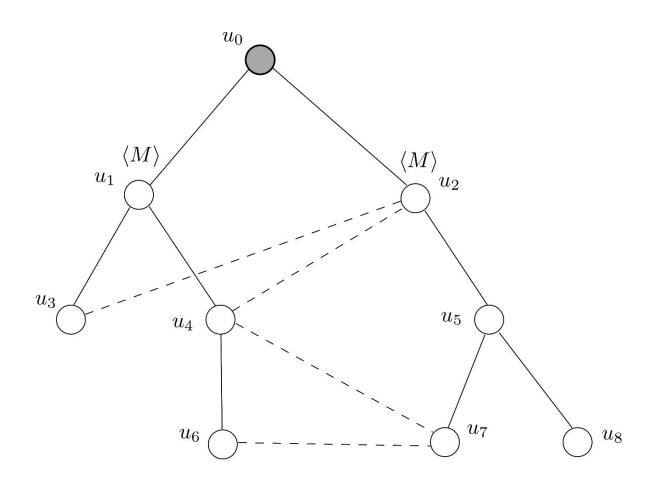

send (M) to all children

terminate

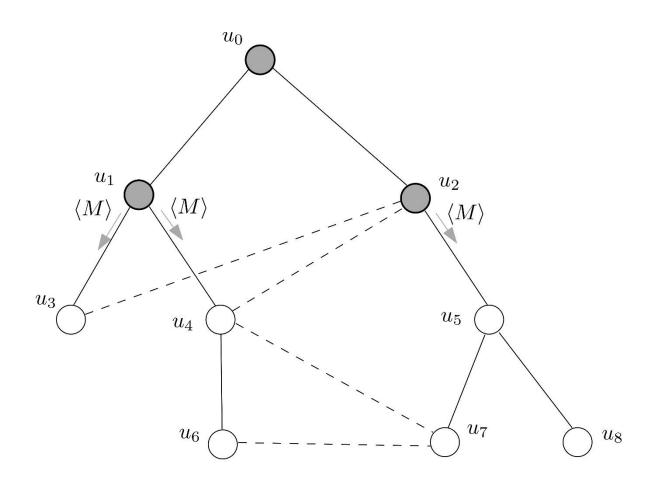

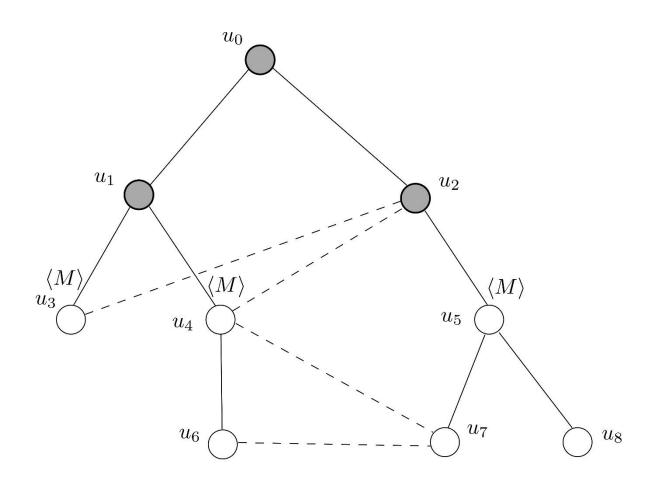

round = 1

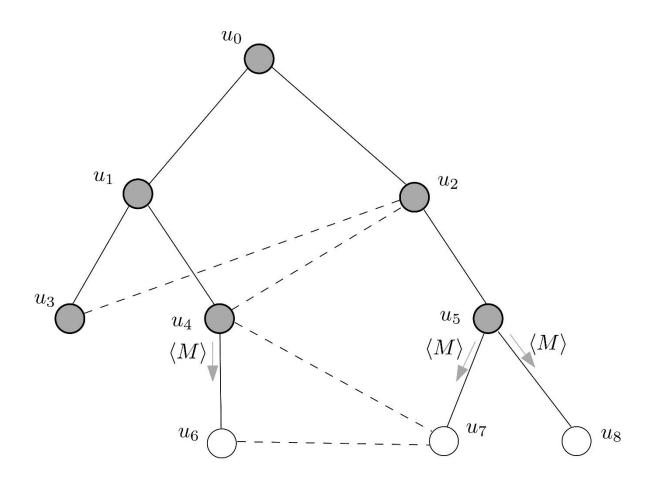

round = 1

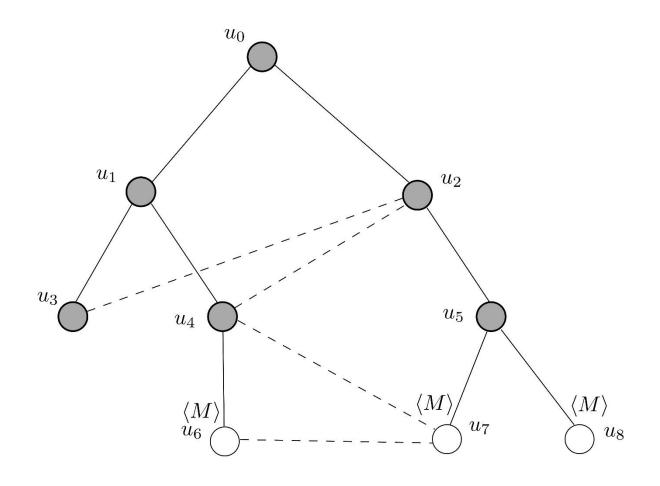

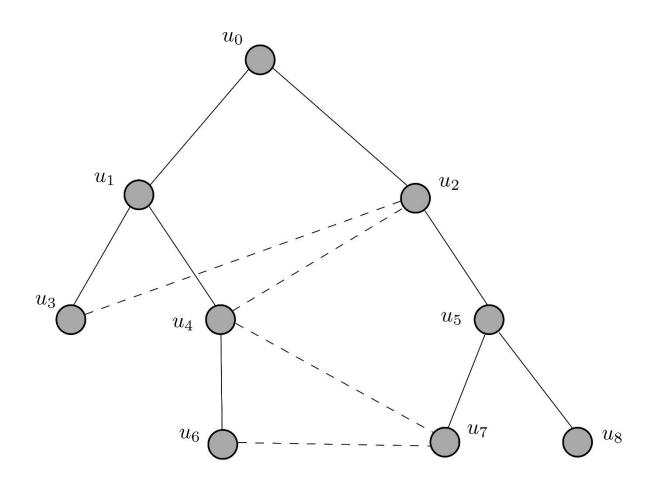

round = 2

round = 3

round = 3

round = 4

#### Correctness and Performance

When we devise an algorithm we typically should

- 1. Convince that it is correct
- 2. Analyse its performance
- Correctness:
  - Usually a proof that the algorithm does as expected
- Performance:
  - Time Complexity (e.g., #rounds required)
  - Space Complexity (e.g., memory used by processors)
  - Communication Complexity (e.g., total #messages transmitted, size of messages); also called message complexity

## **Spanning Tree Broadcast Correctness**

#### Fairly easy for this algorithm:

- Show that every node will receive (M) and terminate
  - Whenever a  $u_i$  receives  $\langle M \rangle$  it terminates by the end of that round
  - Suffices to show that every  $u_i$  will receive  $\langle M \rangle$

**Proof.** Take any  $u_i \neq u_0$ . As the tree T is spanning, there is a single tree-path from  $u_0$  to  $u_i$ . By the way the algorithms works,  $\langle M \rangle$  will be forwarded hopby-hop on the path until it reaches  $u_i$ . And this holds for all  $u_i$  in the network.

Equal to the #rounds until all nodes have received (M)

Lemma. For every  $u_i$  whose distance from  $u_0$  in the spanning tree is r, it holds that  $u_i$  receives  $\langle M \rangle$  in round r. *Proof.* By induction on r.

- For r = 1: Holds because in round 1,  $u_0$  transmits  $\langle M \rangle$  to all its children who receive it in round 1
- Assume that it holds for any  $r 1 \ge 1$ 
  - Means that all processors at distance r 1 receive  $\langle M \rangle$  in round r 1
- Then it must hold also for r
  - The parent  $u_i$  of any  $u_i$  at distance r is at distance r-1
  - By previous assumption, the parent received  $\langle M \rangle$  in round r-1, therefore transmits it to all its children including  $u_j$  in round r, and  $u_j$  receives it in round r

- This means that for a tree T of depth d the algorithm requires d rounds
- But in general we want our algorithm to run on all possible networks and all their possible spanning trees
  - And not all have the same depth...
- What is the worst-case time complexity of our algorithm?

- This means that for a tree T of depth d the algorithm requires d rounds
- But in general we want our algorithm to run on all possible networks and all their possible spanning trees
  - And not all have the same depth...
- What is the worst-case time complexity of our algorithm?
- It is the worst-case depth of a spanning tree on n nodes

- This means that for a tree T of depth d the algorithm requires d rounds
- But in general we want our algorithm to run on all possible networks and all their possible spanning trees
  - And not all have the same depth...
- What is the worst-case time complexity of our algorithm?
- It is the worst-case depth of a spanning tree on n nodes = n 1

1. Size of largest message transmitted?

- 1. Size of largest message transmitted?
  - Size of (M), typically in bits

 For example, if (M) is a single processor identifier (or id) this would typically be O(log n) bits

2. Total #messages transmitted?

- A single observation suffices
- Any ideas?

- 2. Total #messages transmitted?
- A single observation suffices

Observation. For every edge of the spanning tree, from a parent  $u_i$  to a child  $u_j$ , exactly one message will be ever transmitted through it.

- The single transmission of  $\langle M \rangle$  from  $u_i$  to  $u_j$
- As  $u_i$  then terminates it will not happen again
- What is the total #messages then?

- 2. Total #messages transmitted?
- A single observation suffices

Observation. For every edge of the spanning tree, from a parent  $u_i$  to a child  $u_j$ , exactly one message will be ever transmitted through it.

- The single transmission of  $\langle M \rangle$  from  $u_i$  to  $u_j$
- As  $u_i$  then terminates it will not happen again
- What is the total #messages then?
  - #edges of a spanning tree on n nodes
  - Always n 1

### Spanning Tree Broadcast Summing-up

Theorem. The Spanning Tree Broadcast algorithm solves the broadcast problem in any connected synchronous network G when a rooted spanning tree T of G is known in advance. The time complexity of the algorithm (in rounds) is equal to the depth d of T. For the communication complexity, the algorithm transmits a total of n - 1 messages and the maximum size of a message is equal to the binary representation of the information to be broadcast.

# Broadcast without a given Spanning Tree

#### Problem:

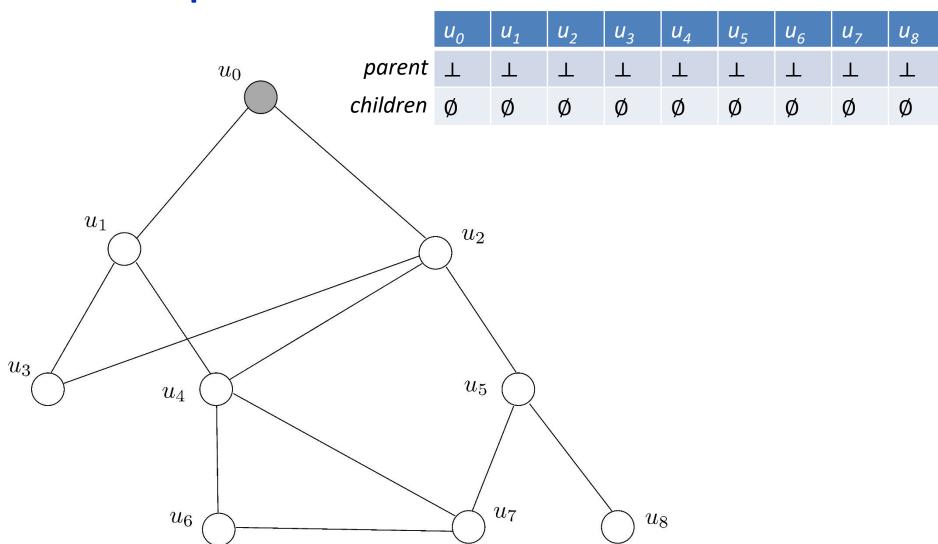

- u<sub>0</sub> has some information it wishes to send to all processors
  - e.g., a message (M)
  - additionally all nodes must have terminated in the end
- No spanning tree of the network G is given in advance
- The algorithm should also output a constructed spanning tree of G

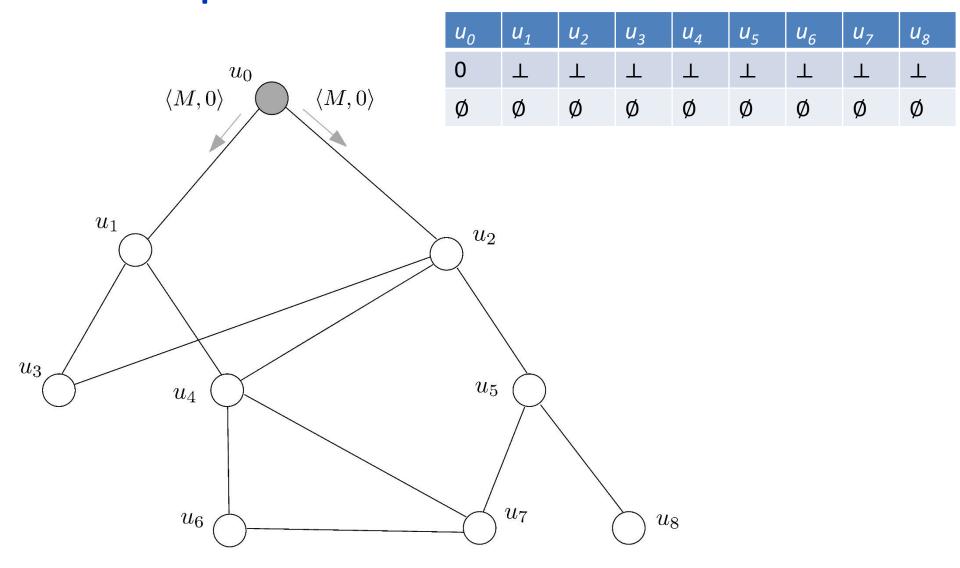

## Solution: Informal description

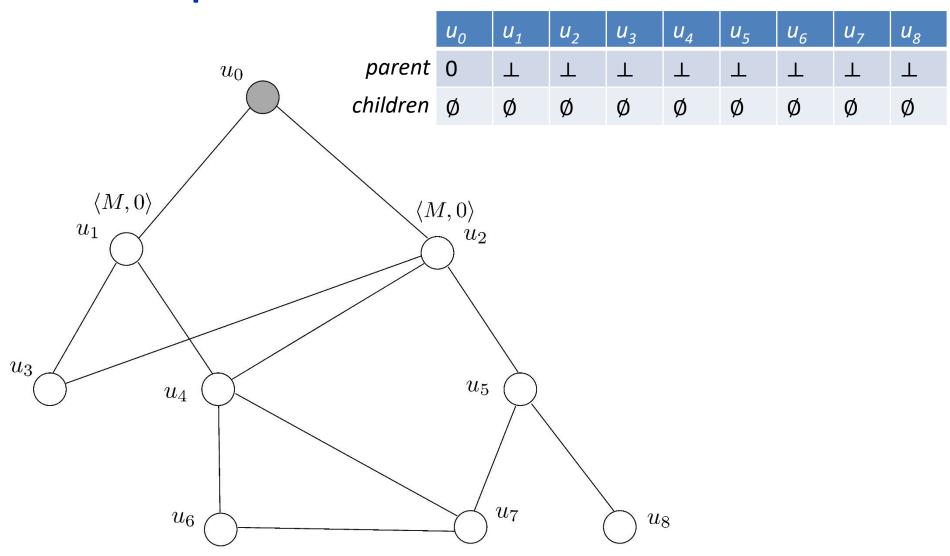

- All nodes awake initially
- If awake and have just received (M) from some neighbours,
  - Choose one of those neighbours as your parent and let him know
  - forward  $\langle M \rangle$  to the rest of the neighbours
  - Wait for 1 round to collect children (if any) and then sleep
- If neighbours inform you that you are their parent,
  - add those processors to your children list
  - sleep
- If you are asleep, do nothing

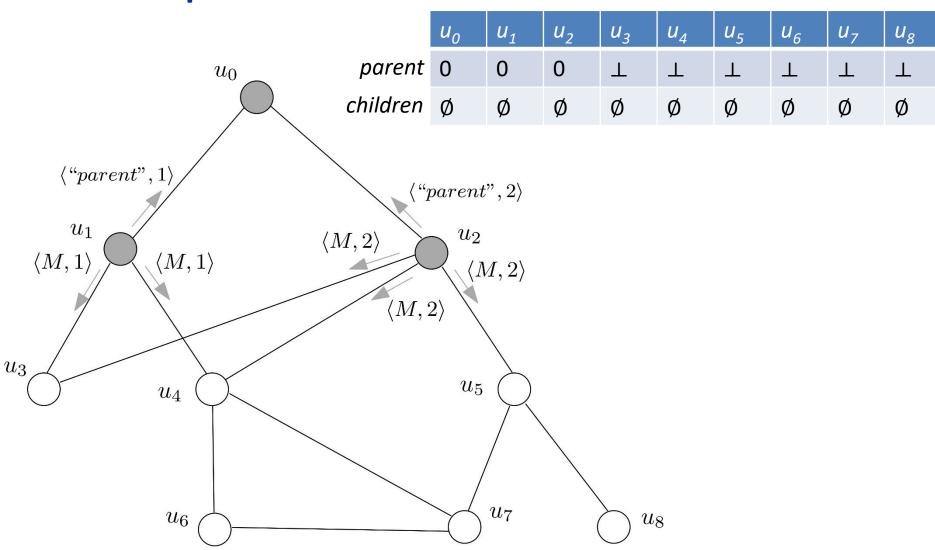

## Solution: Pseudocode

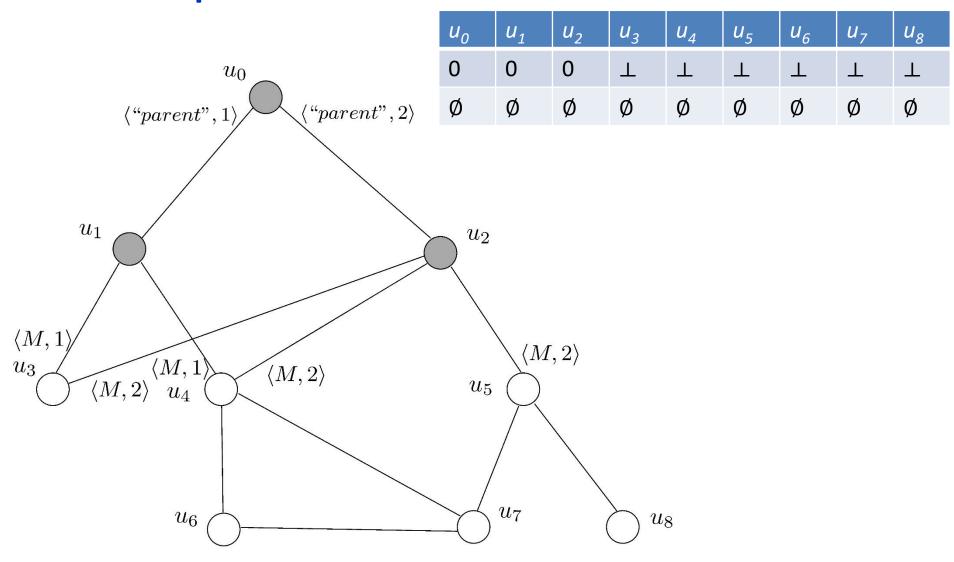

```
Algorithm Broadcast & Spanning tree construction
Code for processor u_i, i \in \{0, 1, ..., n - 1\}:
Initially parent = \perp and children = \emptyset
if u_i = u_0 and parent = \perp then
                                          // root has not yet sent (M)
  send (M) to all neighbours
  parent := u_i
upon receiving (M) from neighbours N:
  if parent = \bot then
                                            // u_i has not received (M) before
    parent := u_i \in N
                                            // select one arbitrarily as parent
    send ("parent") to u_i
     send \langle M \rangle to all neighbours except those in N
     wait for one round to collect children if any and then terminate
upon receiving ("parent") from neighbours N:
  add all u_i \in N to children
  terminate
```

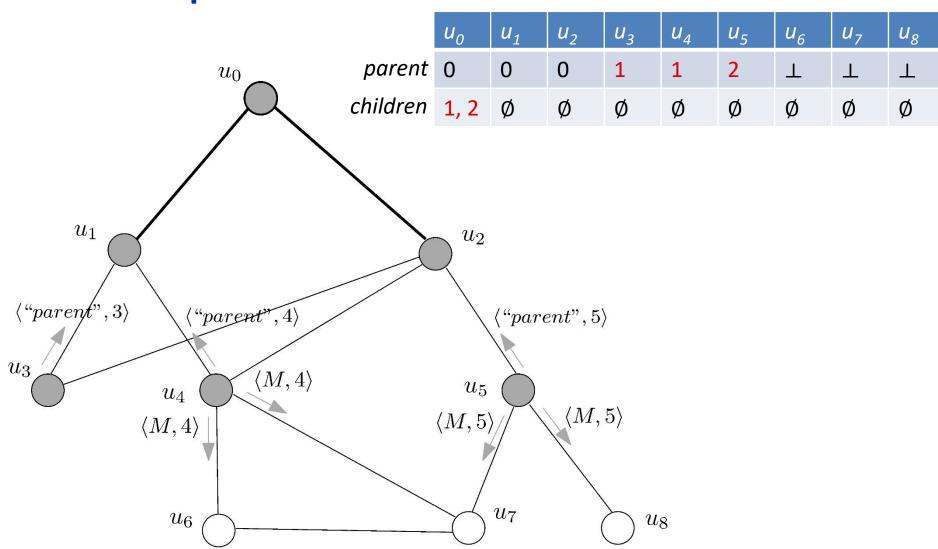

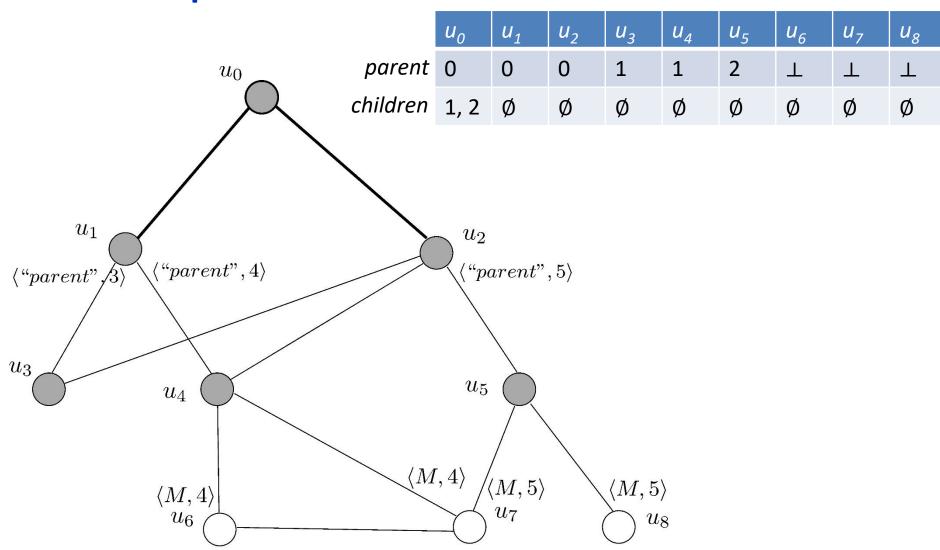

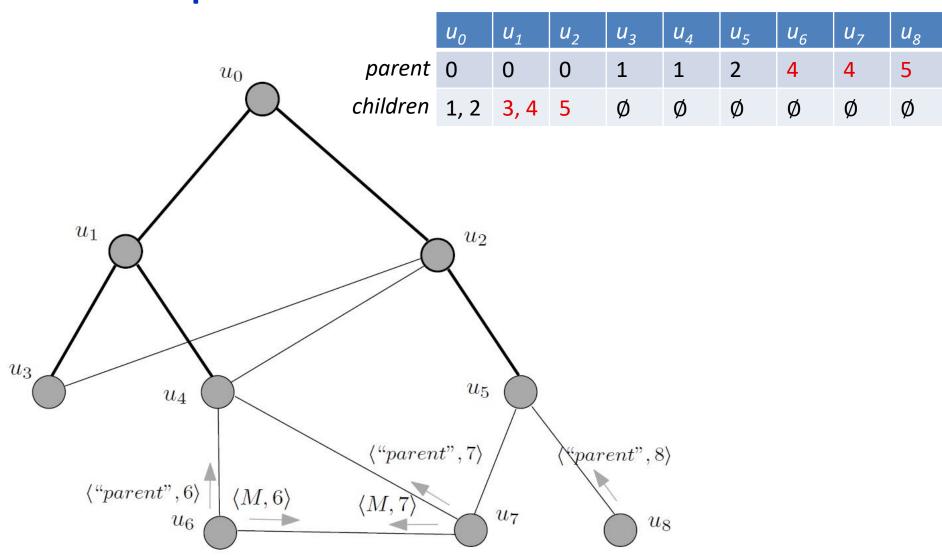

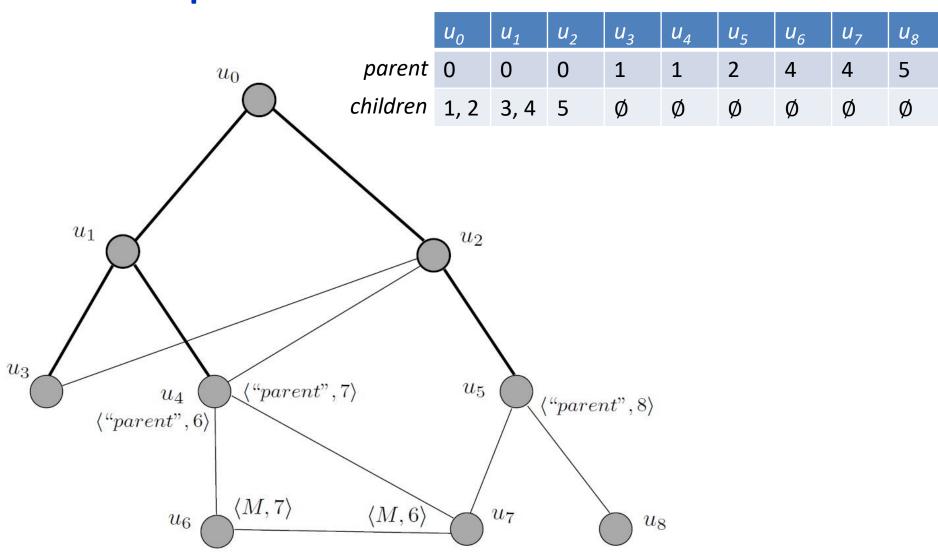

round = 2

34/41

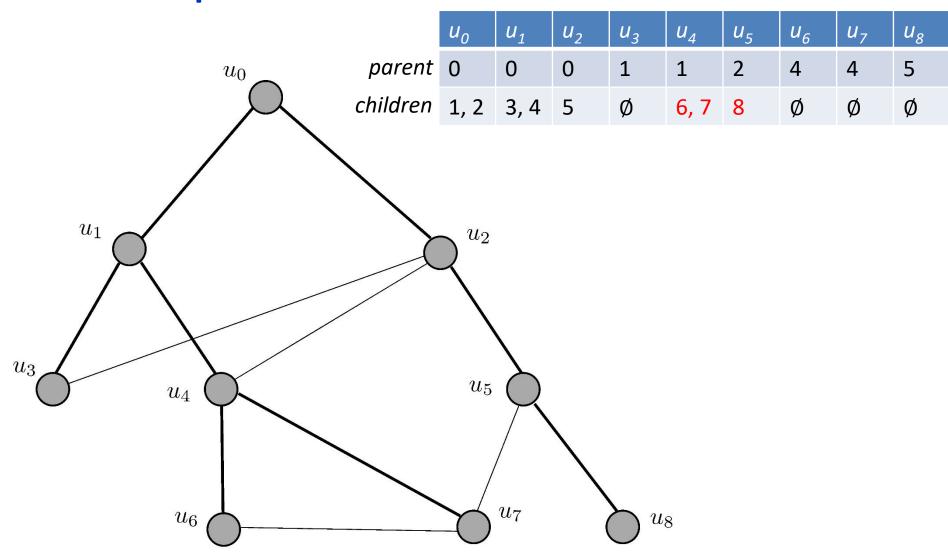

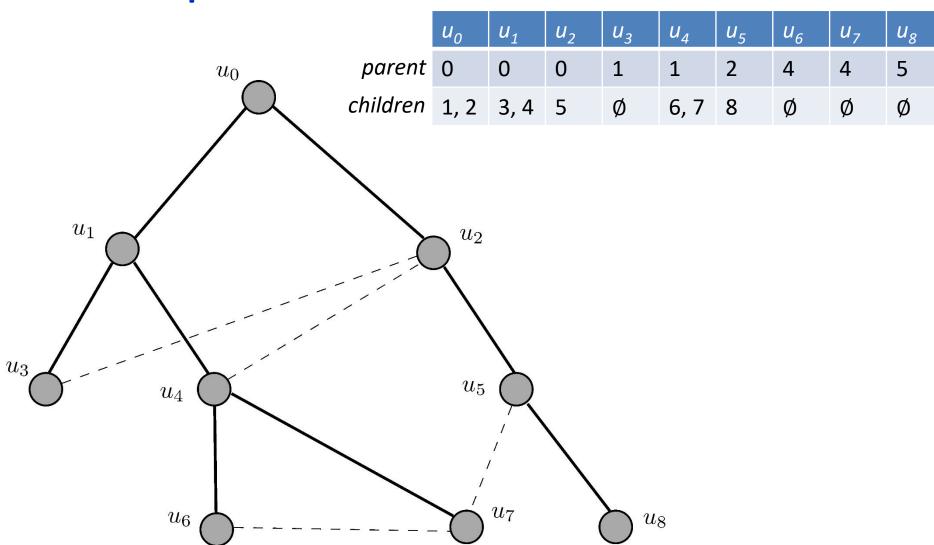

round = 4

38/41

## **Correctness and Complexity**

#### Correctness:

- correctness of broadcast
- correctness of spanning tree construction
  - can also be shown that the constructed tree is always a Breadth-first search (BFS) tree
- Time complexity:
  - O(D): where D is the maximum distance of a  $u_i$  form  $u_0$  in G
- Communication complexity:
  - size of messages: sends message (M) and an id
  - -O(m) messages: where m denotes the #edges of G

Can you prove these at home?
